

AbstractID:8463Title:Improvement of proton energy in laser-driven proton acceleration

Purpose: To improve the energy output of the laser-driven proton accelerator. To investigate how target position and thickness influence the final proton energy. To identify which set of laser parameters are most crucial to obtain higher proton energies.

Method and Materials: The experimental setup for generation of laser-accelerated protons has been redesigned. The laser system is a chain of amplifiers capable of delivering up to 25 TW in a 40 fs pulse. The high-power laser pulses are delivered to a thin ($7\ \mu\text{m}$ – $20\ \mu\text{m}$) Al or 7.5 μm polyamide ($\text{C}_{22}\text{H}_{10}\text{O}_4\text{N}_2$)_n target in a shielded vacuum chamber. When the laser beam is focused by an off-axis parabolic mirror of focal length of 15 cm, the light intensity on the target exceeds $2 \times 10^{19}\ \text{W}/\text{cm}^2$. All experiments are conducted at an oblique (45°) incidence with p-polarized light. The energy of the generated protons is sampled by a range filter and the transmitted beam is registered on a CR39 track detector.

Results: The proton spectra from targets with varying thickness and composition have been recorded. The maximum proton energy in excess of 2 MeV was obtained for a 15 μm Al target situated 50 μm behind the focal plane of the laser beam. Comparison study in 7 μm Al and 7.5 μm polyamide target has been conducted, resulting in slightly higher proton flux from the aluminum target and no measurable energy difference. Applying a simplified heat-transfer model to the target deformation we estimated that the laser prepulse is at a level sufficient to destroy Al targets with thickness below 14.5 μm .

Conclusion: The acceleration of protons using 25 TW ultra-short laser pulses to energies in excess of 2 MeV has been experimentally demonstrated. The influence of various interaction parameters on the final proton energy has been evaluated. These experimental results are a new step toward the generation of therapeutic proton beams with controlled characteristics using lasers.
